Actual values in each of the four bands for nine pixels on the ground. These values are for an area immediately adjacent to the village of Baghestan in the Tauran Plain.

time over which such changes are taking place, and there is a body of mathematical techniques for doing precisely that.

In some ways this is paradoxical. One tends to think first of the satellite data in spatial terms: their similarity to maps or aerial photographs. Yet their greatest importance will probably prove to be in the time dimension. In fact the satellite data provide previously unattainable control over spatial and temporal variation simultaneously. Whether the sort of analysis of long-term processes based on short-term samples of change is feasible with existing technology or not, it is a new way of thinking about change which will eventually be greatly stimulated by the 'new way of seeing' which satellite data represent.

Christopher L. Hamlin teaches archaeology and quantitative methods in the Anthropology Department of the University of Pennsylvania, where he is Assistant Professor. He is Assistant Curator in the Near Eastern Section of the University Museum, with responsibility for Mesopotamian collections. His interest in ancient Near Eastern pastoral adaptations led him to questions about how spatial and temporal variation in the resources used by pastoralists affect the determination of decision strategies, and in turn to the Turan Biosphere Reserve where it may be possible to begin answering these and related questions. He is presently collaborating on the publication of Godin Tepe, a Bronze Age city excavated in western Iran by the Royal Ontario Museum.

Acknowledgments
The assistance of Mr. Tony Patti, Mr. Andrew Weiss, and the staff of the Computer Facility of the Moore School of Electrical Engineering, University of Pennsylvania, in performing data processing tasks related to this project is gratefully acknowledged.

INDEX FOR VOLUME 22 1979-80
